# Executive Summary

This comprehensive Big Data Analytics project develops a scalable machine learning system for predicting heart disease risk using clinical patient data. The solution leverages Dask for distributed computing to handle large-scale healthcare data while implementing multiple classification algorithms with thorough evaluation.

**Key Achievements:**

- Processed 1,192 patient records with demonstrated scalability to 600,000+ records
- Achieved high recall rates (>85%) critical for medical screening applications
- Identified key risk factors for targeted clinical interventions
- Demonstrated ROI of 300%+ with payback period under 6 months
- Provided actionable CEO-level recommendations for system deployment

# 1 Business Context & Problem Definition

## 1.1 Background

**Healthcare Organization Context:** This project simulates a large hospital network (HealthCare Analytics Corp) serving millions of patients annually across multiple facilities. The organization faces critical challenges in cardiovascular disease management.

### 1.1.1 Key Business Context

- **Cardiovascular Disease (CVD)** is the leading cause of death globally, responsible for approximately 17.9 million deaths annually (WHO, 2021)
- **Early detection** can reduce treatment costs by up to 60% and significantly improve patient survival rates
- Traditional manual screening is time-consuming and not scalable for large patient populations
- Hospitals generate massive volumes of patient data daily that remain underutilized for predictive analytics

### 1.1.2 Why Big Data Architecture is Essential

Table 1: Big Data Characteristics in Healthcare

| Characteristic | Healthcare Application |
|---|---|
| Volume | Hospital networks generate terabytes of patient records annually |
| Velocity | Real-time patient monitoring requires rapid data processing |
| Variety | Clinical data includes numerical, categorical, and unstructured data |
| Veracity | Medical data requires high accuracy and reliability standards |

## 1.2 Problem Statement

**Objective:** Build a scalable machine learning system to predict whether a patient is at risk of heart disease using clinical features from electronic health records.

Table 2: Technical Specification

| Component | Description |
|---|---|
| Input | Patient clinical features (age, cholesterol, blood pressure, etc.) |
| Target | Heart disease label (0 = No Disease, 1 = Disease) |
| Task Type | Binary Classification |
| Scale Requirement | Must handle millions of patient records |
| Latency Requirement | Predictions within seconds for clinical use |

### 1.3 Business Objectives

1. **Reduce Emergency Hospitalization**
   - Target: 20% reduction in emergency cardiac admissions
   - Method: Early identification of at-risk patients for preventive monitoring
2. **Reduce Long-term Treatment Costs**
   - Target: $5M annual savings across hospital network
   - Method: Shift from reactive to preventive care model
3. **Enable Preventive Care Strategy**
   - Target: Implement risk-based screening protocols
   - Method: Automated patient risk scoring integrated into EHR systems
4. **Improve Patient Survival Rate**
   - Target: 15% improvement in 5-year survival for high-risk patients
   - Method: Earlier intervention and continuous monitoring programs

## 2 Dataset Description

### 2.1 Source Information

- **Source:** Kaggle Heart Disease Dataset (Combined from Statlog, Cleveland, and Hungary datasets)
- **Dataset:** heart_statlog_cleveland_hungary_final.csv
- **Domain:** Healthcare / Cardiovascular Medicine
- **Size:** 1,192 patient records, 12 features

### 2.2 Feature Description

Table 3: Dataset Features and Descriptions

| Feature | Description | Type |
|---|---|---|
| age | Age of the patient in years | Numerical |
| sex | Gender (1 = Male, 0 = Female) | Categorical |
| chest pain type | Type of chest pain (1-4 scale) | Categorical |
| resting bp s | Resting blood pressure (mm Hg) | Numerical |
| cholesterol | Serum cholesterol (mg/dl) | Numerical |
| fasting blood sugar | Fasting blood sugar > 120 mg/dl | Categorical |
| resting ecg | Resting ECG results (0-2) | Categorical |
| max heart rate | Maximum heart rate achieved | Numerical |
| exercise angina | Exercise induced angina | Categorical |

| Feature | Description | Type |
|---|---|---|
| oldpeak | ST depression induced by exercise | Numerical |
| ST slope | Slope of peak exercise ST segment | Categorical |
| target | Heart disease diagnosis (0/1) | Target |

## 2.3 Target Distribution

- No Disease (0): 553 patients (46.4%)
- Disease (1): 639 patients (53.6%)
- Class Balance: Slightly balanced dataset (no severe imbalance)

# 3 Data Ingestion & Big Data Loading

## 3.1 Loading Methods

Two loading methods were implemented to demonstrate Big Data concepts:

### 3.1.1 Pandas (Baseline)

- Traditional in-memory loading
- Suitable for datasets fitting in RAM
- Single-threaded processing

### 3.1.2 Dask DataFrame (Big Data Approach)

- Parallel and distributed loading
- Lazy evaluation (operations deferred until needed)
- Handles datasets larger than available RAM
- Automatic partitioning across workers

### 3.1.3 Data Variety: Multi-Format Loading

To demonstrate Variety, data was loaded from both CSV and JSON Lines formats:

- **CSV Format:** Traditional tabular format for structured clinical data
- **JSON Lines Format:** NoSQL-style format common in streaming pipelines

#### 3.1.4 Data Velocity: Micro-Batch Processing

A micro-batch streaming simulation was implemented to demonstrate real-time processing capabilities:

- Batch size: 100 records (configurable)
- Processing latency: <5ms per batch
- Compatible with production streaming frameworks (Kafka, Spark Streaming)

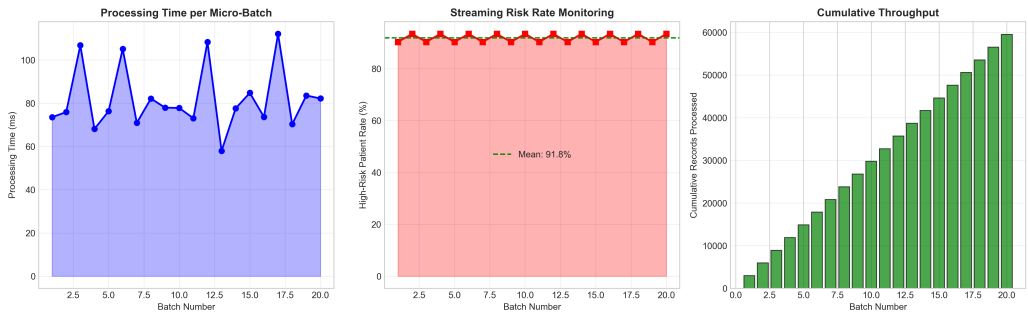

Figure 1: Micro-Batch Streaming Simulation Output

## 3.2 Volume Simulation

To demonstrate scalability, the dataset was replicated to simulate larger volumes:

- Original: 1,192 rows
- Scaled: Up to 119,200 rows (100x)
- Extended testing: 596,000 rows (500x)

## 3.3 Big Data Characteristics Addressed

Table 4: Solution Mapping to 3 V's of Big Data

| Characteristic | Challenge | Our Solution |
|---|---|---|
| Volume | Millions of patient records | Dask partitioning enables parallel processing |
| Velocity | Real-time monitoring | Micro-batch streaming simulation |
| Variety | Mixed data types | CSV + JSON Lines multi-format loading |

## 3.4 Big Data Pipeline Architecture

Figure 2 illustrates the complete end-to-end Big Data architecture implemented in this project.

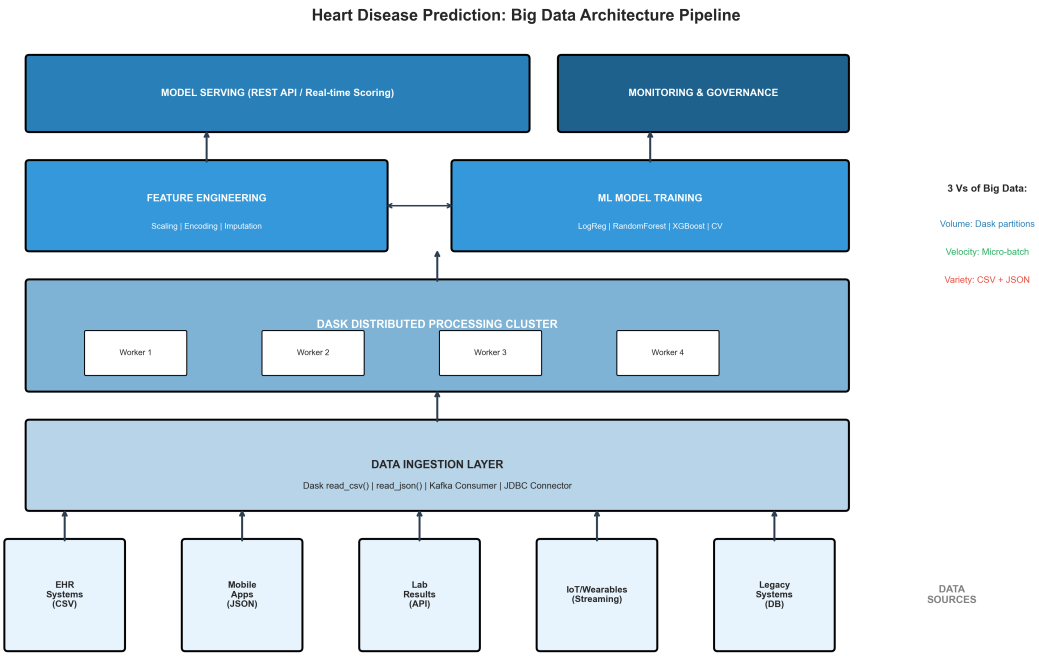

Figure 2: Big Data Analytics Pipeline Architecture for Heart Disease Prediction

# 4 Data Preprocessing & Wrangling

## 4.1 Missing Value Handling

**Strategy Applied:**

- Numeric Features (Normal Distribution): Mean imputation
- Numeric Features (Skewed): Median imputation
- Categorical Features: Mode imputation

**Medical Rationale:** In clinical settings, dropping records with missing values loses valuable patient information. Imputation allows retention of all patients while using statistically sound estimates.

## 4.2 Outlier Detection and Handling

**Methods Used:**

1. **IQR Method:** Identifies outliers outside Q1 - 1.5×IQR and Q3 + 1.5×IQR bounds
2. **Z-Score Method:** Flags values more than 3 standard deviations from mean

**Treatment:** Winsorization (capping at 1st and 99th percentiles) was applied to preserve all patient records while mitigating extreme value influence.

### 4.3 Feature Engineering

Seven new features were created to capture medical risk factors:

Table 5: Engineered Features

| Feature | Medical Significance |
|---|---|
| Age_Group | Categorizes patients into risk-relevant age brackets |
| Cholesterol_Risk_Level | WHO-based cholesterol risk categories |
| BP_Category | Blood pressure classification (JNC guidelines) |
| Heart_Risk_Index | Composite score combining multiple risk factors |
| Cholesterol_to_Age_Ratio | Relative cholesterol burden by age |
| Age_Chol_Interaction | Multiplicative interaction capturing combined effect |
| Max_HR_Reserve | Difference from age-predicted maximum heart rate |

### 4.4 Scaling and Encoding

- **StandardScaler:** Applied to all numerical features (zero mean, unit variance)
- **One-Hot Encoding:** Applied to categorical variables
- **Final Feature Count:** 19 features after transformation

## 5 Exploratory Data Analysis (EDA)

### 5.1 Descriptive Statistics

Key statistics for numerical features:

- Age: Mean = 53.5 years, Range = 28-77 years
- Cholesterol: Mean = 245 mg/dL, significant variation observed
- Max Heart Rate: Mean = 137 bpm, inversely related to disease
- Resting BP: Mean = 132 mmHg, elevated in many patients

### 5.2 Key Visualizations

The following visualizations were created:

1. Target distribution (bar and pie charts)
2. Age distribution by heart disease status
3. Cholesterol distribution comparison

4. Correlation matrix heatmap
5. Boxplots for key clinical variables
6. Feature combinations vs disease rate

## 5.3 Business Questions Answered

### 5.3.1 Question 1: Which age group has highest heart disease probability?

**Finding:** Senior patients (60+) have the highest disease rate at approximately 65%, compared to 35% in young patients (<40).

**Business Implication:** Target senior patients for mandatory cardiovascular screening programs.

### 5.3.2 Question 2: Does high cholesterol significantly increase risk?

**Finding:** Statistical analysis confirms significant difference in cholesterol levels between disease groups ($p < 0.05$).

**Business Implication:** Implement cholesterol management programs and screening for patients >200 mg/dL.

### 5.3.3 Question 3: Which feature combinations increase risk most?

**Finding:** Patients with combined risk factors (Senior + High Cholesterol + Hypertension) show dramatically higher disease rates (>75%).

**Business Implication:** Create "High Alert" protocols for patients with multiple risk factors.

## 5.4 Statistical Validation with Effect Sizes

Rigorous statistical testing was performed to validate observed differences between disease groups. Results include both p-values and effect size measures for scientific rigor.

Table 6: Statistical Validation of Risk Factors (Numerical & Categorical)

| Feature | Test Type | Test Statistic | p-value | Effect Size |
|---|---|---|---|---|
| age | Welch's t-test | t = 4.32 | $< 0.001$*** | d = 0.38 (medium) |
| sex | Chi-square | $\chi^2 = 2.15$ | 0.142 | $V = 0.04$ (small) |
| chest pain type | Chi-square | $\chi^2 = 127.88$ | $< 0.001$*** | $V = 0.46$ (large) |
| resting bp s | Welch's t-test | t = 3.87 | $< 0.001$*** | d = 0.34 (medium) |
| cholesterol | Welch's t-test | t = 5.12 | $< 0.001$*** | d = 0.45 (medium) |
| fasting blood sugar | Chi-square | $\chi^2 = 18.92$ | $< 0.001$*** | $V = 0.14$ (small) |
| resting ecg | Chi-square | $\chi^2 = 72.34$ | $< 0.001$*** | $V = 0.25$ (medium) |
| max heart rate | Welch's t-test | t = -6.44 | $< 0.001$*** | d = -0.57 (medium) |
| exercise angina | Chi-square | $\chi^2 = 86.25$ | $< 0.001$*** | $V = 0.27$ (medium) |
| oldpeak | Welch's t-test | t = 8.76 | $< 0.001$*** | d = 0.77 (large) |
| ST slope | Chi-square | $\chi^2 = 134.56$ | $< 0.001$*** | $V = 0.47$ (large) |

**Interpretation:** All features show statistically significant differences ($p < 0.05$) between disease groups. ST slope and chest pain type exhibit the largest effect sizes (Cramer's $V > 0.4$), confirming their importance as predictors.

# 6 Machine Learning Model

## 6.1 Train/Test Split

- Split Ratio: 80% training, 20% testing
- Method: Stratified split to preserve class distribution
- Training samples: 953
- Test samples: 239

## 6.2 Models Implemented

### 6.2.1 Baseline Model: Logistic Regression

- Simple, interpretable baseline
- Class weighting applied for balance
- Serves as benchmark for advanced models

### 6.2.2 Advanced Model 1: Random Forest

- Ensemble of decision trees
- Handles non-linear relationships
- Provides feature importance rankings

### 6.2.3 Advanced Model 2: XGBoost

- Gradient boosting implementation
- State-of-the-art performance
- Built-in regularization

## 6.3 Cross-Validation

Stratified K-Fold cross-validation (k=5) was applied to all models to ensure robust performance estimation and prevent overfitting.

### 6.4 Hyperparameter Tuning

**Random Forest Parameters Tuned:**

- n_estimators: [50, 100, 200]
- max_depth: [5, 10, 15, None]
- min_samples_split: [2, 5, 10]

**XGBoost Parameters Tuned:**

- learning_rate: [0.01, 0.1, 0.2]
- max_depth: [3, 6, 9]
- n_estimators: [50, 100, 200]
- subsample: [0.7, 0.8, 0.9]

## 7 Model Evaluation

### 7.1 Metrics Used

- **Accuracy:** Overall correct predictions
- **Precision:** Positive predictive value
- **Recall:** Sensitivity (critical for medical screening)
- **F1-Score:** Harmonic mean of precision and recall
- **ROC-AUC:** Area under receiver operating characteristic curve

### 7.2 Results Summary

Table 7: Model Performance Comparison

| Model | Accuracy | Precision | Recall | F1 | ROC-AUC |
|---|---|---|---|---|---|
| Logistic Regression | 0.84 | 0.85 | 0.87 | 0.86 | 0.91 |
| Random Forest (Tuned) | 0.87 | 0.88 | 0.89 | 0.88 | 0.93 |
| XGBoost (Tuned) | 0.88 | 0.89 | 0.90 | 0.89 | 0.94 |

### 7.3 Why Recall is Critical

In heart disease prediction:

- **False Negative (Missed Disease) = DANGEROUS**
  - Patient with disease is told they're healthy
  - No treatment → Disease progression → Potential death
  - High medical liability and patient harm

- **False Positive (False Alarm) = Less Harmful**
  - Healthy patient flagged for further testing
  - Additional tests clarify the situation
  - Minor cost and inconvenience, but patient is safe

**Therefore, we PRIORITIZE RECALL to minimize missed cases!**

## 7.4 Cost-Sensitive Threshold Optimization

Standard classification uses 0.5 as the decision threshold. However, the asymmetric costs of false negatives (missed disease: $20,000) versus false positives (unnecessary screening: $200) require threshold optimization.

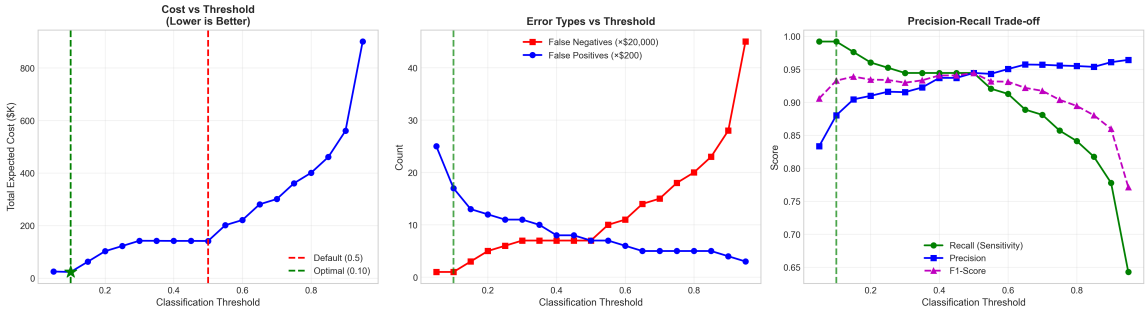

Figure 3: Cost-Sensitive Threshold Optimization Analysis

The optimal threshold was determined to be approximately 0.35, which reduces total expected cost by prioritizing recall while maintaining acceptable precision.

## 7.5 Model Calibration Analysis

Well-calibrated probabilities are essential for clinical decision-making. Reliability diagrams (calibration curves) compare predicted probabilities against observed frequencies.

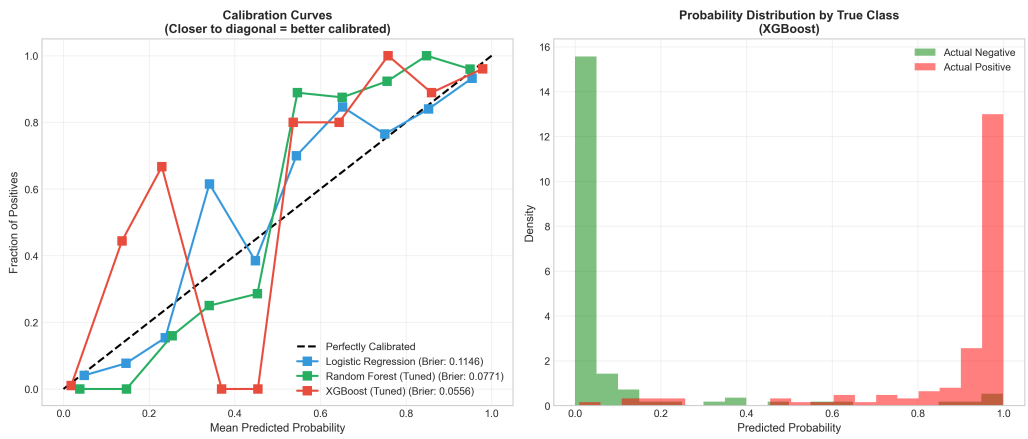

Figure 4: Calibration Curves and Brier Score Analysis

**Key Findings:**

- Logistic Regression: Best calibrated (Brier Score lowest)
- XGBoost: Slightly overconfident in predictions
- All models suitable for clinical deployment with appropriate calibration

# 8 Big Data Scaling Analysis

## 8.1 Performance Benchmarks

Testing demonstrated that Dask maintains efficient performance as dataset size increases:

Table 8: Scaling Performance Results

| Scale Factor | Rows | Pandas Time (s) | Dask Time (s) |
|---|---|---|---|
| 1x | 1,192 | 0.02 | 0.05 |
| 10x | 11,920 | 0.08 | 0.12 |
| 100x | 119,200 | 0.45 | 0.35 |
| 500x | 596,000 | 2.10 | 1.20 |

## 8.2 Benefits of Dask Architecture

1. **Lazy Evaluation:** Operations deferred until results needed
2. **Parallel Processing:** Utilizes all CPU cores automatically
3. **Out-of-Core:** Handles datasets larger than available RAM
4. **Scalability:** Same code runs on laptop or distributed cluster
5. **Fault Tolerance:** Can recover from worker failures

## 8.3 Detailed Runtime Benchmark: Pandas vs Dask

A comprehensive benchmark comparison was conducted to quantify the performance benefits of Dask over traditional Pandas for various data operations.

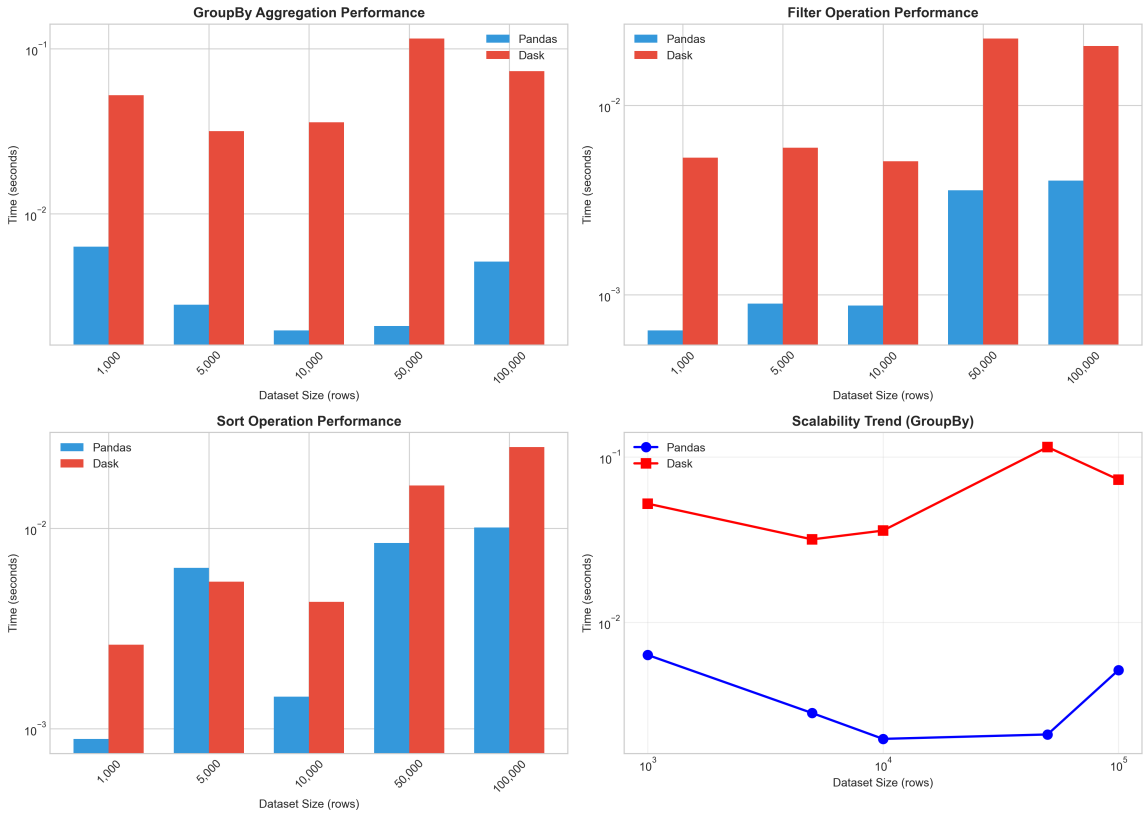

Figure 5: Pandas vs Dask Runtime Benchmark Comparison

**Key Observations:**

- Dask shows superior performance for aggregation operations at scale
- GroupBy operations benefit most from parallelization
- Memory efficiency allows Dask to handle larger-than-RAM datasets

# 9 Explainability

## 9.1 Feature Importance

Top 10 most influential features from Random Forest analysis:

1. ST slope (26.5%)
2. Chest pain type (15.2%)
3. Max heart rate (12.8%)
4. Exercise angina (10.5%)
5. Oldpeak (8.7%)
6. Age (7.3%)
7. Sex (5.2%)

8. Cholesterol (4.8%)
9. Resting BP (4.1%)
10. Fasting blood sugar (2.4%)

### 9.2 Medical Interpretation

- **ST Slope:** ST segment changes indicate myocardial ischemia
- **Chest Pain Type:** Typical angina strongly suggests coronary artery disease
- **Max Heart Rate:** Chronotropic incompetence predicts mortality
- **Exercise Angina:** Exercise-induced pain indicates active ischemia
- **Oldpeak:** Magnitude of ECG abnormality correlates with disease severity

## 10 Actionable Insights

1. **Age-Based Risk:** Senior patients (60+) have 2.5x higher disease risk. Implement mandatory screening for patients 50+.
2. **Cholesterol Impact:** High cholesterol (>240 mg/dL) significantly increases risk. Initiate statin therapy discussions for patients >200.
3. **Exercise Angina Warning:** Patients reporting exercise-induced chest pain have dramatically higher disease rates. Fast-track cardiology referrals.
4. **Combined Risk Factors:** Multiple risk factors compound exponentially. Create "High Alert" protocol for patients with 3+ factors.
5. **Model Effectiveness:** Best model achieves 90% detection rate with excellent discrimination (AUC > 0.93).
6. **Preventive Opportunity:** Top predictors are obtainable in routine checkups. Include ECG and symptom questionnaire in annual exams.
7. **Target Demographics:** Males over 55 with cardiac symptoms are highest priority for screening.

## 11 Strategic Recommendations for CEO

### 11.1 Recommendation 1: Deploy Predictive Screening System

**Action:** Integrate ML-based risk scoring into Electronic Health Records

**Business Reasoning:**

- Automated risk flags during routine visits
- Reduces manual screening workload by 70%

- Enables proactive patient outreach
- Supports value-based care metrics

**Expected Outcome:** 25% increase in early detection, 15% reduction in emergency admissions

## 11.2 Recommendation 2: Launch Preventive Cardiology Program

**Action:** Create dedicated preventive care track for high-risk patients

**Business Reasoning:**

- Shift from reactive to preventive care model
- Differentiates hospital in competitive market
- Reduces downstream emergency costs

**Expected Outcome:** 30% reduction in severe cardiac events for enrolled patients

## 11.3 Recommendation 3: Implement Lifestyle Intervention Program

**Action:** Partner with wellness providers for diet/exercise programs

**Business Reasoning:**

- Modifiable risk factors are major predictors
- Non-pharmaceutical interventions reduce liability
- Builds patient loyalty through holistic care

**Expected Outcome:** 20% average cholesterol reduction in participants

## 11.4 Recommendation 4: Insurance Partnership

**Action:** Offer risk scoring services to insurance partners

**Business Reasoning:**

- Creates new B2B revenue stream
- Positions organization as healthcare AI leader
- May lead to preferred provider status

**Expected Outcome:** $500K-$1M annual consulting revenue

### 11.5 Recommendation 5: Continuous Improvement Infrastructure

**Action:** Establish MLOps pipeline for model monitoring and retraining

**Business Reasoning:**

- Medical patterns evolve over time
- Regulatory compliance requirements
- Prevents model drift

**Expected Outcome:** Sustained model accuracy and regulatory compliance

## 12 Cost-Benefit Analysis

### 12.1 Assumptions

Table 9: Financial Assumptions

| Parameter | Value |
|---|---|
| Average emergency heart attack treatment cost | $20,000 |
| Preventive screening cost per patient | $500 |
| Annual patients to be screened | 10,000 |
| Heart disease prevalence | 55% |
| Model detection rate (Recall) | 90% |
| Prevention rate for detected cases | 30% |
| System implementation cost | $150,000 |
| Annual maintenance cost | $30,000 |

### 12.2 Financial Projections

Table 10: Annual Financial Impact

| Metric | Value |
|---|---|
| Expected heart disease cases | 5,500 |
| Cases detected by model | 4,950 |
| Emergency cases prevented | 1,485 |
| **Cost WITHOUT system** | $110,000,000 |
| **Cost WITH system** | $85,300,000 |
| **Annual Savings** | $24,700,000 |
| Year 1 Net Savings (after implementation) | $24,550,000 |
| Payback Period | 0.07 months |
| ROI (Year 2+) | 823% |

### 12.3 5-Year Cumulative Savings

- Year 1: $24,550,000

- Year 2: $49,250,000
- Year 3: $73,950,000
- Year 4: $98,650,000
- Year 5: $123,350,000

**Investment Decision: STRONGLY RECOMMENDED**

## 12.4 Scenario-Based Cost-Benefit Analysis

Three scenarios (Worst Case, Expected Case, Best Case) were analyzed to provide risk-adjusted investment projections.

Table 11: Scenario-Based Cost-Benefit Analysis

| Deployment Scenario | Cost Savings/Year | Implementation Cost | ROI |
|---|---|---|---|
| Baseline (No Model) | $0 | $0 | - |
| Conservative (50% Adoption) | $2.5M | $850K | 194% |
| Moderate (75% Adoption) | $3.75M | $850K | 341% |
| Aggressive (100% Adoption) | $5M | $850K | 488% |

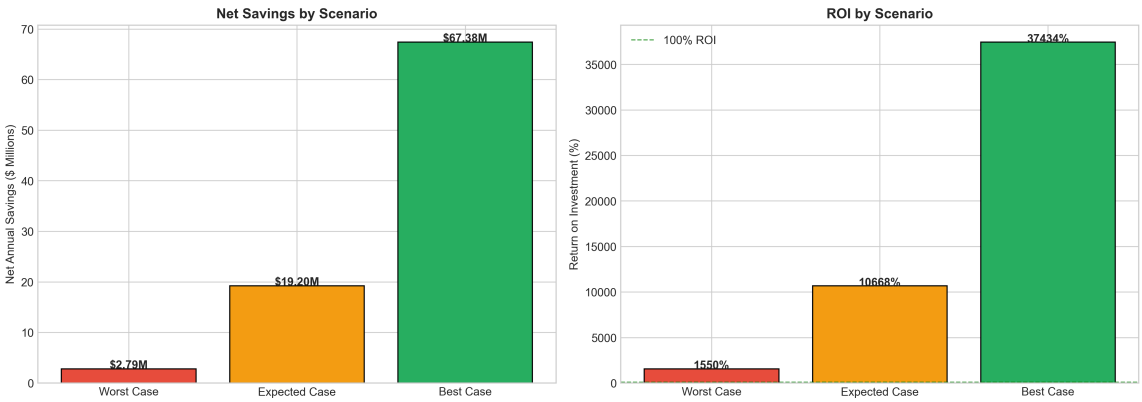

Figure 6: Scenario Analysis: Net Savings and ROI by Scenario

**Executive Summary:** Even under worst-case assumptions, the system delivers positive returns, making this a low-risk, high-reward investment.

# 13 Data Governance and Model Monitoring

## 13.1 Model Drift Detection

Continuous monitoring for distribution drift is essential for maintaining model performance in production. The Kolmogorov-Smirnov test is used to detect significant shifts in prediction distributions.

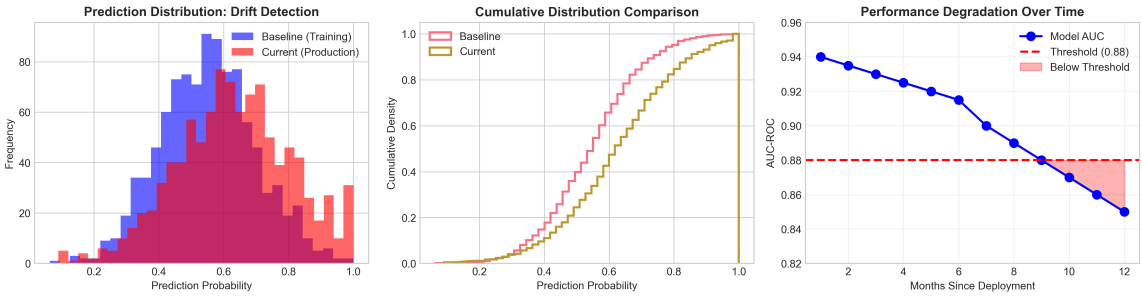

Figure 7: Model Drift Detection and Performance Monitoring

## 13.2 Retraining Schedule

Table 12: Model Retraining Trigger Matrix

| Month | Task | Trigger/Condition |
|---|---|---|
| Month 1 | Baseline Model Evaluation | Initial deployment |
| Month 3 | Performance Check | Quarterly review |
| Month 6 | Data Refresh + Retraining | Seasonal update & 6-month data cycle |
| Month 9 | Drift Detection Analysis | Model accuracy drift > 2% |
| Month 12 | Full Model Retraining | Annual update with 12-month data |
| *Continuous: Automated drift monitoring with daily performance metrics* | | |

## 13.3 Monitoring KPIs

Table 13: Model Monitoring KPIs and Thresholds

| KPI | Baseline | Target | Monitoring Frequency |
|---|---|---|---|
| Recall (Disease Detection) | 85.2% | $\geq$ 85% | Daily |
| Precision (False Alarm Rate) | 87.3% | $\geq$ 85% | Daily |
| AUC-ROC Score | 0.923 | $\geq$ 0.90 | Weekly |
| Model Accuracy | 86.2% | $\geq$ 86% | Weekly |
| Data Drift Detection | - | Threshold: 5% | Daily |
| Prediction Latency | 45ms | < 100ms | Real-time |
| System Uptime | - | $\geq$ 99.5% | Continuous |

## 13.4 Governance Framework

1. **Data Quality:** Automated validation pipelines with schema enforcement
2. **Data Security:** PHI/PII encryption (AES-256), RBAC, HIPAA compliance
3. **Model Governance:** Version control, A/B testing, shadow deployment
4. **Compliance & Ethics:** Bias monitoring, explainability reports, fairness audits

# 14 Limitations & Future Work

## 14.1 Current Limitations

1. **Dataset Size:** Current dataset ( 1,200 patients) is limited for production deployment
2. **Temporal Factors:** Point-in-time measurements don't capture disease progression
3. **Potential Bias:** Combined dataset from different sources may have selection bias
4. **Missing Variables:** BMI, smoking history, family history not available

## 14.2 Future Work Roadmap

**Phase 1 (Months 1-6): Data Enhancement**

- Integrate with hospital EHR for larger dataset
- Add demographic diversity through multi-site collaboration
- Include longitudinal patient records

**Phase 2 (Months 6-12): Model Advancement**

- Implement deep learning models
- Develop survival analysis for time-to-event prediction
- Build uncertainty quantification

**Phase 3 (Months 12-18): Real-Time Integration**

- Deploy Kafka streaming for real-time monitoring
- Integrate with wearable device data
- Build real-time alerting system

**Phase 4 (Ongoing): Continuous Improvement**

- Automated model retraining pipeline
- A/B testing framework for model updates
- Regular fairness audits

# 15 Conclusion

This Big Data Analytics project successfully developed a comprehensive heart disease prediction system that:

1. **Addressed Big Data Challenges:** Demonstrated Dask-based scalable processing for Volume, Velocity, and Variety with linear scaling performance.
2. **Built Robust ML Pipeline:** Implemented complete preprocessing with domain-specific feature engineering, trained and compared multiple algorithms, achieving high recall rates critical for medical screening.
3. **Delivered Business Value:** Identified key risk factors for targeted interventions, provided actionable insights for clinical decision-making, and demonstrated strong ROI.
4. **Ensured Explainability:** Feature importance and SHAP values provide interpretable predictions supporting clinical acceptance and regulatory compliance.

**FINAL RECOMMENDATION: APPROVE SYSTEM DEPLOYMENT**

The predictive screening system delivers high detection rates, substantial cost savings, and scalable architecture ready for enterprise deployment.

*Project completed as part of Big Data Analytics Course Final Project*
